Anonymous Source Verification System

Candidate Brief — Confidential

Objective

Build a prototype system that verifies evidence from anonymous sources and generates a public, privacy-preserving certificate with ready-to-use attribution language. The core challenge: how do you prove that a piece of evidence is genuine and has not been tampered with? Anyone can hash a file after creating it. Your system must solve for provenance.

Sample Data

Build and test your prototype against the following evidence package.

> **Scenario: Academic Misconduct Allegation**
>
> A postdoctoral researcher alleges that her principal investigator fabricated data in a published gene therapy paper. The source has requested full anonymity.

- **journalist_intake_notes.txt** — Journalist's summary and initial assessment.
- **email_chain_vasquez_hargrove.txt** — Email correspondence between source and accused.
- **recorded_conversation_march_19.mp3** — Audio recording with a corroborating witness.
- **data_comparison_memo.txt** — Quantitative comparison of raw data vs. published values.
- **vasquez_personal_notes.txt** — Personal notes kept by the source.

Deliverables

Prioritize based on the time available. What you choose to build — and what you choose to cut — is part of the assessment.

1. Marketing Page

Explain the problem, the solution, and how it works. Show an example certificate. Clear call to action.

2. Evidence Capture & Verification Engine

Design and prototype a system for handling evidence from anonymous sources. Your architecture should address how evidence enters the system, how its authenticity is established, and how it is analyzed. The engine should assess consistency, corroboration, and plausibility across evidence, classify reliability, and return structured output. No sensitive source data should be exposed.

3. Certificate & Attribution Output

Generate a privacy-preserving certificate (ID, timestamp, confidence score, evidence breakdown) and publication-ready attribution language that journalists can copy directly into their reporting.

> **Example attribution:**
> *"The internal review process was bypassed entirely," said a source verified via Objection's independent certification process.*

Time & Submission

> **This is a rapid execution task.** A couple of hours should be enough. Please submit within a couple of days.

- Deployed link (Vercel, Netlify, Replit, or similar).
- Source code (GitHub or equivalent).
- 2–3 minute Loom walkthrough.
- One paragraph describing your AI workflow and tools.

Good luck. We look forward to seeing what you build.
